Peptide Perspectives

RECHARGING THE CELL

The Emerging Science of Peptides & Mitochondrial Energy

WHY CELLULAR ENERGY MATTERS

- Mitochondria help convert nutrients and oxygen into **ATP**, the cell's usable energy.
- They also influence **metabolism**, **calcium balance**, **stress signaling**, and **cell survival**.
- Impaired mitochondrial function can affect **muscles**, **heart**, and **metabolic health**.
- More energy markers do not automatically equal more real-world energy or less fatigue.

HOW CELLS MAKE, PROTECT & RENEW ENERGY

ATP PRODUCTION
Oxidative phosphorylation in mitochondria.

AMPK
Cellular fuel gauge (senses energy status and adapts metabolism).

CARDIOLIPIN
Inner-membrane architecture and mitochondrial organization.

HUMANIN
- Stress-response and cell-survival signaling.

NAD+
Redox balance and cellular maintenance (energy and repair support).

GLUTATHIONE
Antioxidant defense (helps neutralize oxidative stress).

L-CARNITINE
Fatty-acid transport into mitochondria (for energy production).

MITOPHAGY / QUALITY CONTROL
Recycling damaged mitochondria (mitochondrial renewal).

Mitochondrial health is not one pathway — it is fuel delivery, energy conversion, stress sensing, membrane protection, and quality control.

EIGHT COMPOUNDS RESEARCHERS ARE EXPLORING

ESTABLISHED / STRONGEST CLINICAL GROUNDING

SS-3[+] (ELAMIPRETIDE)
- Cardiolipin-binding peptide.
- FDA accelerated approval in Barth syndrome only.

NAD+
- Central energy coenzyme.
- Human precursor studies but inconsistent functional results.

L-CARNITINE
- Fuel transport into mitochondria.
- Established in deficiency states (e.g., primary or secondary carnitine deficiency).

PRECLINICAL OR MIXED HUMAN EVIDENCE

MOTS-c
- Mitochondrial-derived peptide.
- AMPK-related metabolic adaptation (shown mainly in preclinical and early human studies).

HUMANIN
- Cell-survival and stress signaling.
- Promising preclinical data; administered human benefit not established.

GLUTATHIONE
- Tripeptide involved in antioxidant defense.
- May help manage oxidative stress (evidence is mixed and context-dependent).

EXPERIMENTAL RESEARCH TOOLS / EARLY EVIDENCE

5-AMINO-1MQ
- NNMT inhibition (may influence cellular metabolism).
- Not a peptide; primarily a research compound.

AICAR
- AMPK-related research tool (activates AMPK).
- Not approved for energy enhancement (used mainly in research settings).

WHAT THE EVIDENCE SUGGESTS

- **SS-31** has the clearest regulatory milestone, but only in a narrow rare-disease population.
- **MOTS-c** and **Humanin** are exciting, but administered-human benefit is not established.
- Raising **NAD**-related markers does not guarantee better function or vitality.
- **L-carnitine** works best where deficiency or specific need exists.

WHERE THE SCIENCE IS HEADING

- Match therapies to the right mitochondrial problem.
- Measure real-world outcomes, not just biomarkers.
- Study mitochondrial renewal and communication.
- Integrate exercise, sleep, nutrition, and recovery.

EVIDENCE TAKEAWAY

- Biological plausibility is not the same as proven clinical benefit.
- Regulatory approval for one mitochondrial therapy does not validate all compounds.
- Some compounds are peptides; others are related nutrients or research molecules.
- Educational overview only; investigational compounds are not established general energy enhancers.
